Effect of Sowing Date and Harvesting Date on the Performance of Autumn Sown Sugarbeets Springer

A field experiment entitled "Effect of sowing date and seeding rate on growth, yield and quality of summer mungbean cultivars" was conducted at Tirhut College of Agriculture, Agronomy Farm, Dholi of Rajendra Agricultural University, Pusa, Bihar in during 2006. The growth parameter recorded at different growth stages exhibited the influence of different treatments. Significant

influence of seed rate and varieties on height were recorded till grand growth phase (60 DAS). Number of branches was also positively influenced by date of sowing and cultivars whereas increase in seed rate recorded reduced number of branches. The effective leaves per plant was significantly and positively influenced by early sowing (25th March) but seed rate could not influence in definite direction. 10th April sowing had significant and positive effect on dry matter accumulation till 60 DAS and cultivar Samart recorded to be most efficient in dry matter production.

Effects of date of sowing on the yield and yield components of spring wheat and their relationship with solar radiation and temperature at Ludhiana, Punjab, India: Long version CIMMYT
Yield response of three wheat (*Triticum aestivum* L.) cultivars (Gemnieza 7, Sakha 93 and Giza 168) to various sowing times was studied during the two 2006/2007 and 2007/2008 seasons. Three sowing dates were 5th November, 20th November, and 5th December. A split-split plot design was used. Wheat plants were sown on 20th November gave the highest values of the most of characteristics such as plant height, leaf area index, crop growth rate, spike length, number of spikes m⁻², 1000- kernel weight, grain yield (Mg ha⁻¹), harvest index and protein grains content in both seasons. Increasing N- fertilization rates up to 288 kg N ha⁻¹ led to increased growth parameters, yield and yield components. 288 kg N ha⁻¹ recorded the highest values of the most parameters in both seasons. Gemnieza 7 had highest values for most of growth characters, yield and its components compared with the other cultivars (Sakha 93 and Giza 168). Sowing on 20 Nov. with 288 kg N ha⁻¹ had significantly increased on most

studied characteristics. There was no fungal diseases infection as affected by different sowing dates and nitrogen fertilization level of the three wheat cultivars during two sowing seasons.

Effect of Sowing Dates and Topping on Seed Yield and Seed Quality of Jute Varieties LAP Lambert Academic Publishing

The experimental treatments were laid down in a split plot design with three replications to determine the effects of sowing date, seeding rate & varieties on the yield & yield components of rice. Three sowing date treatments were assigned to main plots; while factorial combinations of three seeding rates & three rice varieties (X-Jigna, Gumara and Superica- 1) were randomly allocated to subplots. Variety X- Jigna produced significantly higher number of panicles/0.5 m row than Gumara & Superica-1, whereas Superica-1 & X-Jigna produce comparable number of spiklets per panicle which was significantly greater than that of Gumara. The third sowing date gave the highest harvest index than the other two sowing dates. Compared to the other varieties X-Jigna exhibited the highest harvest index. Similarly 75kg/ha seeding rate gave the highest harvest index compared with the remaining two seeding rates. Based upon the present study findings it may be tentatively recommended that variety Supereica-1 should be planted 10 days after the farmers planting time. On the 3rd sowing date, both X-Jigna & Gumara resulted in higher grain yields at a seeding rate of 75kg/ha.

The Effect of Sowing Date on the Growth and Yield of Winter Barley LAP Lambert Academic Publishing

In connection with the study of variety agrotechnology referable to a new variety of soft wheat, Bol-bugda that has been released

to the rayons and which is definitely more promising for dry farming areas, for a period of three years we made a study of one of the important factors: the effect of sowing date on growth, development and yield of this variety.

Effect of Sowing Dates on Rice Seedling Characters LAP Lambert Academic Publishing

Agronomic crops have been used to provide foods, beverages, fodders, fuels, medicines and industrial raw materials since the dawn of human civilization. Today, agronomic crops are being cultivated by employing scientific methods instead of traditional methods. However, in the current era of climate change, agronomic crops are subjected to various environmental stresses, which results in substantial yield loss. To meet the food demands of the ever-increasing global population, new technologies and management practices are being adopted to boost yield and maintain productivity under both normal and adverse conditions. Scientists are now exploring a variety of approaches to the sustainable production of agronomic crops, including varietal development, soil management, nutrient and water management, pest management, etc. Researchers have also made remarkable progress in developing stress tolerance in crops through different approaches. However, achieving optimal production to meet the increasing food demand is an open challenge. Although there have been numerous publications on the above-mentioned problems, and despite the extensive research being conducted on them, there is hardly any comprehensive book available. In response, this book offers a timely resource, addressing all aspects of production technologies, management practices and stress tolerance in

agronomic crops in a single volume.

Effect of Sowing Dates and Cuttings on Seed Yield and Quality in Oat (Avena Sativa L.) [With CD Copy] LAP Lambert Academic Publishing

Effect of genotype, planting date, and year on yield, yield components and phenology; Effect of PTQ, temperature, and solar radiation on yield and GM2 during pre-anthesis; Absolute and relative losses with delayed sowing; Statistical analysis; Effect of genotype, planting date, and year on yield, yield components, and phenology; Effect of PTQ, temperature, and solar radiation on yield and GM2 during pre-anthesis; Effect of temperature and solar radiation during post-anthesis period on grain yield and TGW; Use of the PTQ for explaining year effects; Absolute and relative losses with delayed sowing.

The Effects of Sowing Date on Forage Yield and Composition of Oats, Barley and Wheat Grown Under Irrigation in Saudi Arabia Rice (*Oryza sativa* L.) is the most important crop of south east Asia popularly referred to as the rice bowl of the world. India has the largest area under rice in the world it ranks second in production falling far behind China, which has production of about 200 m tons. The reason for very low productivity in Bihar centres round the fact that rice cultivation in Bihar is mostly rain dependent. Both raising nursery and transplanting seedlings are on the mercy of monsoon, which is extremely erratic in onset, distribution, intensity and cessation. Invariably the seedlings overgrow in the nursery awaiting for rains adequate to perform puddling operations. As a result of use of overgrown seedlings, at times, the crop starts flowering soon after flowering reducing the yield tremendously. Some of the times it becomes even difficult

to raise seedlings due to very delayed and erratic monsoon. A very large number of herbicides are there which have been observed to have effective control of weeds in direct seeded rice. However, selecting a particular herbicide or its combination with mechanical weed management require thorough probe.
